Finding the Vertex using Symmetry & the y-intercept

Recall: 1. factored form: y = a(x - s)(x - t)

2. standard form: y = a(x - s)(x - t)

2010

In factored form, s and t are the **exces** .

In standard form, c is the <u>y-intercept</u>.

To find the vertex from standard form, we normally factor and solve for the zeroes.

Apr 19-7:41 PM

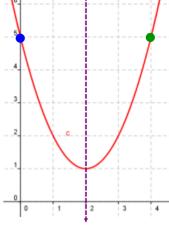

This graph has the equation $y = y^2 + 4y + 5 = 6y$

$$y = x^2 - 4x + 5$$
 (y-int = 5)

In factored form...

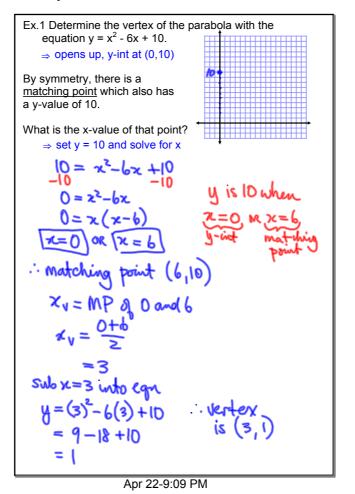

- ... it cannot be factored.
- : there are no zeroes.

How can we find the vertex algebraically?

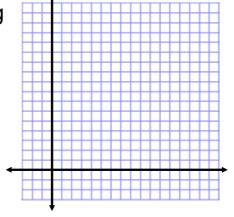

Note that the y-intercept (0,5) has a "matching point" on the other side of the axis of symmetry, at (4,5).

We can use the y-intercept and its matching point to find the vertex of the parabola (just like using the zeroes).

The y-int is (0,10) and the matching point is (6,10).

The axis of symmetry must be halfway between the x-values of 0 and 6.

```
Ex.2 A ball is thrown into the air. Its height, in metres, after t seconds is h = -4.9t^2 + 39.2t + 1.75.

- When does it reach maximum height?

- What is the maximum height?

N-int = 1.75

Sub h = 1.75

1.75 = -4.9t^2 + 39.2t + 1.75

0 = -4.9t^2 + 39.2t

0 = t(-4.9t + 39.2t)
